#### Example

The [2,1] repetition code  $\begin{bmatrix} 0\\1 \end{bmatrix} \begin{bmatrix} 0\\1 \end{bmatrix}$  is quasi-uniform. The induced random variables  $X_1, X_2$  take values 0, 1 such that  $P(X_1 = 0) = P(X_2 = 0) = P(X_{12} = 00) = 1/2.$ But  $P(X_{12} = 01) = P(X_{12} = 10) = 0$  since  $01, 10 \notin \lambda(X_{12})$ .

#### Example

The [2,1] repetition code  $\begin{bmatrix} 0 & | & 0 \\ 1 & | & 1 \end{bmatrix}$  is quasi-uniform. The induced random variables  $X_1, X_2$  take values 0, 1 such that  $P(X_1 = 0) = P(X_2 = 0) = P(X_{12} = 00) = 1/2.$ But  $P(X_{12} = 01) = P(X_{12} = 10) = 0$  since  $01, 10 \notin \lambda(X_{12}).$ 

#### Example

Consider the code 
$$\begin{bmatrix} 0 & 0 \\ 0 & 1 \\ 1 & 0 \end{bmatrix}$$
. Here  $|\lambda(X_1)| = 2$  but the probabilities  
 $P(X_1 = 0) = 2/3, P(X_1 = 1) = 1/3$ . Hence the code is not quasi-uniform.

#### Definition

A group G is a set endowed with a binary operation satisfying:

- **1** *G* is closed under the binary operation
- In the binary operation is associative
- There exists an identity element 1 such that 1g = g1 = g for every  $g \in G$
- Output States States

#### Definition

A group G is a set endowed with a binary operation satisfying:

- **(**) *G* is closed under the binary operation
- In the binary operation is associative
- There exists an identity element 1 such that 1g = g1 = g for every  $g \in G$
- Output State St

### Definition

Given a subgroup  $G_i$  of G, a left coset (respectively right) of  $G_i$  in G is defined as

$$gG_i = \{gh, h \in G_i\}$$
 respectively  $G_ig = \{hg, h \in G_i\}$ .

#### Theorem (Chan, Yeung, 2002)

<sup>2</sup> For any finite group G and subgroups  $G_1, \ldots, G_n$ ,  $\exists$  n quasi-uniform discrete random variables  $X_1, \ldots, X_n$  such that  $\forall \mathcal{A}$  of  $\mathcal{N} = \{1, \ldots, n\}$ ,  $P(X_{\mathcal{A}} = x_{\mathcal{A}}) = 1/[G : G_{\mathcal{A}}] = |G_{\mathcal{A}}|/|G|$ ; where  $G_{\mathcal{A}} = \cap_{i \in \mathcal{A}} G_i$ .

X - a random variable uniformly distributed over G.  $X_i = XG_i$ , the  $[G : G_i]$  cosets of  $G_i$ .

<sup>&</sup>lt;sup>2</sup> T. H. Chan and R. W. Yeung, "On a Relation Between Information Inequalities and Group Theory", 2002. Equation Sector 2018

#### Theorem (Chan, Yeung, 2002)

<sup>2</sup> For any finite group G and subgroups  $G_1, \ldots, G_n$ ,  $\exists$  n quasi-uniform discrete random variables  $X_1, \ldots, X_n$  such that  $\forall \mathcal{A}$  of  $\mathcal{N} = \{1, \ldots, n\}$ ,  $P(X_{\mathcal{A}} = x_{\mathcal{A}}) = 1/[G : G_{\mathcal{A}}] = |G_{\mathcal{A}}|/|G|$ ; where  $G_{\mathcal{A}} = \cap_{i \in \mathcal{A}} G_i$ .

X - a random variable uniformly distributed over G.  $X_i = XG_i$ , the  $[G : G_i]$  cosets of  $G_i$ .

Corresponding quasi-uniform code can be obtained as follows:

	$G_1$	 Gn		
$1 = g_1$	$g_1G_1=G_1$	$g_1G_n=G_n$		
g <sub>2</sub>	$g_2G_1$	$g_2G_n$		
÷	•	÷		
$g_{ G }$	$g_{ G }G_1$	 $g_{ G }G_n$

Let G be a finite group with subgroups  $G_1, \ldots, G_n$ .

Lemma (Size)

The size of the quasi-uniform code  $|C| = |G|/|G_N|$ ;  $G_N = \cap_{i=1}^n G_i$ .

Proposition (Group Structure)

Quasi-uniform code C has a group structure if all subgroups  $G_i$  are normal.

Let G be a finite group with subgroups  $G_1, \ldots, G_n$ .

Lemma (Size)

The size of the quasi-uniform code  $|C| = |G|/|G_N|$ ;  $G_N = \cap_{i=1}^n G_i$ .

Proposition (Group Structure)

Quasi-uniform code C has a group structure if all subgroups  $G_i$  are normal.

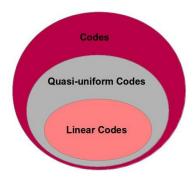

### Lemma (Minimum Distance)

The minimum distance of the quasi-uniform code (having group structure) C is

$$n-\max_{\mathcal{A}\in\mathcal{N},\mathcal{G}_{\mathcal{A}}\neq\{0\}}|\mathcal{A}|.$$

# Quasi-uniform codes:Overview

Using this method, one can construct:

- Codes over non-field alphabets.
- Codes with coefficients over different alphabets.
- Non-linear codes.

# Storage code construction

- Encode a data object into a codeword, spread the coefficients across nodes.
- The code provides fault tolerance in case of node failures.
- Needs to enable repairability.

Suppose a data object  $(u_1, u_2, u_3)$  needs to be stored. Consider the following storage allocation:

node 1:  $(u_1, u_3)$ node 5:  $(u_1 + u_3, u_2 + u_3)$ node 2:  $(u_1, u_2)$ node 6:  $(u_3, 0)$ node 3:  $(u_1, u_2 + u_3)$ node 7:  $(u_1, 0)$ node 4:  $(u_1 + u_3, u_2)$ node 8:  $(u_1 + u_3, 0)$ 

Three failures at most can be tolerated (corresponding to a minimum distance of 4 indeed).

In case of one node failure, this node is repaired easily: indeed, this codeword is created from  $\mathbb{Z}_2\text{-linear}$  combinations. For example:

- node 1 is repaired by downloading  $u_1$  (from node 2 or node 7) and  $u_3$  (from node 6),
- node 2 is repaired by downloading  $u_2$  from node 4 and  $u_1$  (from node 1 or 7).

- A code of length n and dimension k is said to be (n, k, r) locally repairable, if each codeword symbol can be recovered from r other symbols. The integer r; 1 ≤ r ≤ k, is called locality.
- If there exist *t* disjoint recovery sets for each codeword symbol, the code is said to have availability *t*.
- The above construction gives codes with locality and availability, where *t* = *r* = 2.
- It satisfies some bounds for codes with locality and availability.
